Key Words and Phrases: Almost supermartingale, fixed point, urn model

SUMMARY

An urn model of Diaconis and some generalizations are discussed. A convergence theorem is proved that implies for Diaconis’ model that the empirical distribution of balls in the urn converges with probability one to the uniform distribution.
1 Introduction

Diaconis has formulated the following simple urn model.

EXAMPLE 1. Let $G$ be a finite group, generated by $g_1, \ldots, g_r$. Initially, an urn contains $r$ balls, each labeled by one of the generating elements. At times $n = r + 1, r + 2, \cdots$ two balls are drawn with replacement from the urn. The labels on these balls are multiplied to form a new group element. A ball, bearing this element as its label, is then added to the urn, increasing the number of balls in the urn by one. Let $X_k$ be the label indicator with respect to the $k$th ball (i.e., $X_k$ is a vector of length $|G|$, with a one placed in the coordinate associated with the ball’s label and zeros elsewhere.) Let $p_{g,n} = \sum_{k=1}^{n} I\{X_{g,k} = 1\}/n$ denote the relative frequency of balls labeled $g$ when the total number of balls in the urn is $n$. As an application of Theorem 2 below, we verify a conjecture of Diaconis, that $p_{g,n} \to |G|^{-1}$, for all $g \in G$, as $n \to \infty$ with probability one.

EXAMPLE 2. A special case of Example 1 occurs when the balls are numbered either 0 or 1 and the group operation is addition modulo 2. Then $p_n$, the fraction of 1’s in the urn after $n$ draws, converges to 1/2 with probability one. As a variation of this special case one can draw $k \geq 2$ balls from the urn with replacement and add a 0 or a 1 according as the number of 1’s drawn is even or odd. Again the fraction of balls numbered 1 converges to 1/2 with probability one.

EXAMPLE 3. For an example motivated by a classical model in population genetics (e.g. Ewens (1969)), we suppose that the population size in a pure birth process at the $n$th generation is $k_n \geq n$. The population consists of three kinds of individuals corresponding to the three biallelic genotypes AA,
2. CONVERGENCE TO A FIXED POINT

Aa, and aa, which have relative fitness (i.e., probability of reproduction) of $1-s$, $1$, $1-t$, respectively. We assume $s < 1$, $t < 1$. In the most interesting special case $0 < s < 1$, $0 < t < 1$, so the heterozygote Aa has the greatest fitness. Let $p_n$ denote the fraction of A alleles in the population at the $n$ generation. Then under random mating the relative proportions of AA, Aa and aa genotypes that reproduce in the $n+1$st generation are $p_n^2(1-s) : 2p_n(1-p_n) : (1-p_n)^2(1-t)$. We assume that reproduction occurs independently of the population size process. Does the fraction $p_n$ converge and what is its limit? In this example it is natural to assume that $k_n$ grows exponentially, so that the number of balls added to the urn in each generation is comparable to the number of balls already in the urn. One could also add this feature to Examples 1 and 2.

2 Convergence to a fixed point

Consider a finite set $G$. Let $G^*$ be the simplex of probability distributions over $G$ and let $T : G^* \rightarrow G^*$ be a map of the simplex into itself. The point $q \in G^*$ is a fixed point of the transformation if $T(q) = q$. Below we investigate almost-sure convergence of the stochastic sequence of empirical distributions $\{p_n\}$, define by the recursion:

$$p_{n+1} = \frac{k_n}{k_{n+1}} p_n + \frac{\sum_{i=k_{n+1}}^{k_{n+1}} X_i}{k_{n+1}} = \frac{k_0 p_0 + \sum_{i=1}^{k_{n+1}} X_i}{k_{n+1}},$$

where $\{k_n\}$ is a monotone sequence of integer-valued random variable (i.e. $k_{n+1} \geq k_n + 1$, for all $n$), and $X_i$ is a random vector that indicates an element from $G$. The integer $k_0$ is positive and $p_0$ is a given initial distribution vector.
Consider the filtration $F_n = \sigma\{X_1, \ldots, X_{k_n}, k_1, \cdots, k_n, k_{n+1}\}$, for $n \geq 1$. We assume that, conditional on $F_n$,
\[
\sum_{i=k_n+1}^{k_{n+1}} X_i \sim \text{Multinomial}(T(p_n), k_{n+1} - k_n),
\]
and identify sufficient conditions to ensure the convergence of $p_n$ to a contracting (cf. assumption A1 below) fixed point of the transformation $T$.

Our argument is a two-fold application of the almost supermartingale convergence theorem of Robbins and Siegmund (1971). We begin with a statement of that theorem:

**Theorem 1.** Let $Z_n, \xi_n, \zeta_n$ be non-negative random variables adapted to the increasing sequence of $\sigma$-algebras $F_n$. Suppose that for each $n$,
\[
\mathbb{E}(Z_{n+1}|F_n) \leq Z_n + \xi_n - \zeta_n.
\]
Then $\lim Z_n$ exists and is finite and $\sum \zeta_n < \infty$ almost surely on the event where $\sum \xi_n < \infty$.

Our main result relies on the following assumptions on the transformation $T$, the sequence $\{k_n\}$ and the initial distribution $p_0$:

**A1:** The collection $Q = \{q_0, q_1, \cdots, q_J\}$ of fixed points of $T$ is non-empty and finite and the fixed point $q_0$ is contracting, i.e., $\|T(p) - q_0\| < \|p - q_0\|$, for all $p \in G^* - Q$. The point $q_0$ may be in the interior of $G^*$, but all other fixed points are on the boundary (i.e. their supports are proper subsets of $G$).

**A2:** For all $j > 0$ let $c_j$ be a vector with 0’s in those coordinates where $q_J$ has positive mass and 1’s in those coordinates where $q_J$ has no mass.
Assume $c_j$ is not equal to the zero vector (which is equivalent to assuming that $q_j$ is on the boundary of $G^*$). Further assume that $(c_j, p_0) > 0$ and for $p$ not orthogonal to $c_j$, $\inf_{p \rightarrow q_j} \langle c_j, T(p) \rangle / \langle c_j, p \rangle > 1$.

**A3:** The increasing sequence, $k_n$, of random integers satisfies $k_{n+1}/k_n \leq C$, for all $n$ and for some constant $C > 1$ such that $C - 1 < \min\{||q_i - q_j|| : i \neq j\}$.

**Theorem 2.** Under the above assumptions, $p_n \rightarrow q_0$ with probability one as $n \rightarrow \infty$.

**PROOF.** The proof consists of applications of Theorem 1 to (a) $Z_n = ||p_n - q_0||^2$ and (b) $Z_n = 1/\langle c_j, p_n \rangle$. Consider first case (a). Let $\pi_{n+1} = (k_{n+1} - k_n)/k_{n+1}$ and define $\bar{X}_{n+1} = \sum_{i=k_{n+1}}^{k_{n+1}} X_i / (k_{n+1} - k_n)$. Observe that $p_{n+1} - q_0 = (1 - \pi_{n+1})(p_n - q_0) + \pi_{n+1}(\bar{X}_{n+1} - q_0)$. We take the conditional expectation given $\mathcal{F}_n$ of the squared norm of this identity and use the facts that (i) $\mathbb{E}(\bar{X}_{n+1} | \mathcal{F}_n) = T(p_n)$ and (ii) the (conditional) second moment of a random variable is the sum of its variance and the square of its expectation. Then by regrouping terms and using the Cauchy-Schwarz inequality and conditions A1, A3 we see that

\[
\mathbb{E}(Z_{n+1} | \mathcal{F}_n) = Z_n - 2\pi_{n+1}(1 - \pi_{n+1})[Z_n - \langle p_n - q_0, T(p_n) - q_0 \rangle]
+ \pi_{n+1}^2 \mathbb{E}||\bar{X}_{n+1} - T(p_n)||^2 | \mathcal{F}_n | + ||T(p_n) - q_0||^2 - Z_n
\leq Z_n - Z_n k_{n+1} - k_n C \cdot k_n (1 - \frac{||T(p_n) - q_0||}{||p_n - q_0||}) + \frac{k_{n+1} - k_n}{k_{n+1}^2}.
\]

Hence by A1 and Theorem 1, since

\[
\sum_{n=0}^{\infty} \frac{k_{n+1} - k_n}{k_{n+1}^2} \leq \int_0^{\infty} \frac{dx}{x^2} < \infty,
\]
we see that with probability one, \( \lim Z_n \) exists and is finite and the negative terms of the process are summable. By the non-negativity of the terms involved and by the fact that

\[
\sum_{n=0}^{\infty} \frac{k_{n+1} - k_n}{k_n} \geq \int_{k_0}^{\infty} \frac{dx}{x} = \infty,
\]

we can conclude that either \( Z_n \to 0 \) or \( \|T(p_n) - q_0\|/\|p_n - q_0\| \to n \to \infty 1 \). However, only fixed points produce equality in the contraction inequality. Consequently by A3, with probability one \( p_n \) converges to some \( q_j \in Q \), the set of fixed points.

To eliminate the possibility that some \( q_j \) with \( j > 0 \) is the limit, we consider case (b): \( Z_n = \frac{1}{\langle c_j, p_n \rangle} \). Indeed, we let \( A_j = \{p_n \to q_j\} \) and show that \( Z_n \) converges to a finite limit on \( A_j \), which would be a contradiction unless \( P(A_j) = 0 \). This will complete the proof of the theorem since \( p_n \) must converge to a fixed point.

We turn to proving the convergence of \( \{Z_n\} \) on \( A_j \). Define \( \tilde{S}_{n+1} = \langle c_j, \sum_{i=k_n+1}^{k_{n+1}} X_i \rangle \), \( \tilde{p}_n = \langle c_j, p_n \rangle \) and \( \tilde{T}(p_n) = \langle c_j, T(p_n) \rangle \). Note that \( \tilde{p}_{n+1} = [k_n\tilde{p}_n + (k_{n+1} - k_n)\tilde{S}_{n+1}]/k_{n+1} \). Conditional on \( F_n \), \( \tilde{S}_{n+1} \) is the sum of a subset of the coordinates of a multinomial vector and hence is distributed as \( \text{Binomial}(k_{n+1} - k_n, \tilde{T}(p_n)) \). Now

\[
\mathbb{E}[Z_{n+1}|F_n] = \mathbb{E}\left[ \frac{k_{n+1}}{k_n\tilde{p}_n + \tilde{S}_{n+1}} \bigg| F_n \right] = \sum_{s=0}^{k_{n+1}-k_n} \frac{k_{n+1}}{k_n\tilde{p}_n + s} \mathbb{P}(\tilde{S}_{n+1} = s|F_n).
\]

The relations \( \mathbb{P}(\tilde{S}_{n+1} = 0|F_n) = 1 - \sum_{s=1}^{k_{n+1}-k_n} \mathbb{P}(\tilde{S}_{n+1} = s|F_n) \) and \( 1/(k_n\tilde{p}_n + s) - 1/(k_n\tilde{p}_n) = -s/(k_n\tilde{p}_n + s) \cdot 1/(k_n\tilde{p}_n) \) produces

\[
= Z_n + \frac{k_{n+1} - k_n}{k_n\tilde{p}_n} \left[ 1 - \frac{k_{n+1}}{k_{n+1} - k_n} \sum_{s=1}^{k_{n+1}-k_n} \frac{s \cdot \mathbb{P}(\tilde{S}_{n+1} = s|F_n)}{k_n\tilde{p}_n + s} \right]. \tag{2}
\]
We will proceed by showing that on the event \( \tilde{\mathbb{P}}_n \to 0 \supset A_j \) the term in the square brackets is eventually strictly negative. Therefore, the positive part is summable, and Theorem 1 can be used in order to conclude that \( \lim Z_n \) exists and is finite.

We analyze separately the cases: (i) \( \mathbb{E}(\tilde{S}_{n+1}|\mathcal{F}_n) < \epsilon \), (ii) \( \epsilon \leq \mathbb{E}(\tilde{S}_{n+1}|\mathcal{F}_n) \leq M \), and (iii) \( \mathbb{E}(\tilde{S}_{n+1}|\mathcal{F}_n) > M \), for some prespecified \( 0 < \epsilon < M < \infty \) to be determined later.

Consider case (i). By the monotonicity of the function \( x/((a+x)) \) we obtain the inequality
\[
\left[ \cdots \right] \leq \left[ 1 - \frac{k_{n+1}}{k_{n+1} - k_n} \mathbb{P}(\tilde{S}_{n+1} \geq 1|\mathcal{F}_n) \right].
\]

Now, \( \mathbb{P}(\tilde{S}_{n+1} \geq 1|\mathcal{F}_n) = 1 - (1 - \tilde{T}(p_n))^{k_{n+1} - k_n} \geq (k_{n+1} - k_n)\tilde{T}(p_n)(1 - \epsilon/2) \), which leads to the inequality
\[
 \leq \left[ 1 - (1 - \epsilon/2)\frac{k_nT(\tilde{p}_n)}{k_n\tilde{p}_n + 1} \right].
\]

If \( k_n\tilde{p}_n \to \infty \), then assumption A2 will produce a negative limit provided that \( \epsilon \) is small enough.

To prove that \( k_n\tilde{p}_n \to \infty \), it is sufficient to prove that \( \sum_{n=0}^{\infty} I\{\tilde{S}_{n+1} \geq 1\} \) is almost surely infinite. Equivalently, it is enough to show
\[
\sum_{n=n_0}^{\infty} \mathbb{P}(\tilde{S}_{n+1} \geq 1|\mathcal{F}_n) \geq \sum_{n=n_0}^{\infty} (k_{n+1} - k_n)\tilde{p}_n(1 - \epsilon/2) = \infty,
\]
for an appropriate \( n_0 \). However, \( \tilde{p}_n \geq \langle c_j, p_0 \rangle/k_n \), and the statement follows from the fact that \( \{(k_{n+1} - k_n)/k_n \} \) has an infinite sum.

Next consider case (ii). Since \( \tilde{T}(p_n) \to 0 \), we must have that \( k_{n+1} - k_n \to \infty \) and thus \( \tilde{S}_{n+1} \) behaves in distribution like a Poisson random variable.
(conditional on $\mathcal{F}_n$). This time we use the inequality
\[
\sum \leq 1 - \frac{1}{(k_n+1 - k_n)\tilde{p}_n} \mathbb{E} \left( \frac{\tilde{S}_{n+1}}{1 + \tilde{S}_{n+1}/k_n\tilde{p}_n} | \mathcal{F}_n \right).
\]

Case (ii) implies a lower bound on the term $(k_{n+1} - k_n)\tilde{p}_n$ and a stochastic upper bound on the random variable $\tilde{S}_{n+1}$. It follows that the conditional expectation $\sim \mathbb{E}(\tilde{S}_{n+1} | \mathcal{F}_n) = (k_{n+1} - k_n)\tilde{T}(p_n)$, which produces a negative value in the square brackets, by A2.

Finally, consider case (iii). By monotonicity one gets that
\[
\frac{s}{a + s} \geq \frac{y \cdot I\{s \geq y\}}{a + y}
\]
and, upon selecting $y = (1 - \epsilon_1)\mathbb{E}(\tilde{S}_{n+1} | \mathcal{F}_n)$, the inequality
\[
\sum \leq 1 - \frac{k_{n+1}\mathbb{P} (\tilde{S}_{n+1} \geq (1 - \epsilon_1)\mathbb{E}(\tilde{S}_{n+1} | \mathcal{F}_n) | \mathcal{F}_n)}{k_n[\tilde{p}_n/(1 - \epsilon_1)\tilde{T}(\tilde{p}_n)] + (k_{n+1} - k_n)}.
\]

Chernoff’s inequality leads to the upper bound
\[
\left[1 - \frac{k_{n+1}}{k_n[\tilde{p}_n/(1 - \epsilon_1)\tilde{T}(\tilde{p}_n)] + (k_{n+1} - k_n)(1 - e^{-\frac{\epsilon_1 \mu}{x}})}\right].
\]

Selection of a large enough $M$ and a small enough $\epsilon_1$ will lead to a negative limit, provided that $(k_{n+1} - k_n)/k_n$ is bounded. This last condition is assured by assumption A3.

## 3 Applications

**EXAMPLE 1.** In the urn model of Diaconis the transformation takes the form:
\[
(T(p))_g = \sum_{h \in G} p_{g^{-1}h}^{-1}p_h, \quad \text{for } g \in G.
\]
Any uniform distribution over a subgroup is a fixed point of this transformation. Conversely, any fixed point is a uniform distribution over a subgroup. The last statement follows from the fact that the support of a fixed point is a subgroup since the support is closed under group operations and the group is finite. Moreover, by the definition of a fixed point, the probability of each element in the support must be equal to the maximum of all probabilities unless a contradiction is to occur. The collection of uniform distributions over subgroups is finite.

Denote by $q_0$ the uniform distribution over the entire group. Viewing $\left(\sum_{h \in G} p_{g^{-1}h}p_h\right)^2$ as the square of the expectation of the random variable taking on the value $p_h$ with probability $p_{g^{-1}h}$, we obtain from the Cauchy-Schwarz inequality that $\sum_{g \in G} \left(\sum_{h \in G} p_{g^{-1}h}p_h\right)^2 \leq \sum_{g \in G} p_g^2$, with strict inequality unless $p_h$ is constant on its support. From this and direct computations, we see that $T$ is contracting, so condition A1 is met.

Let $G_j$ be a proper sub-group of $G$. Observe that $\langle c_j, p \rangle$ assigns a probability to $G \setminus G_j$. A product of two group elements, one belonging to $G_j$ and the other not belonging, produces a group element not belonging to $G_j$. It follows that

$$\langle c_j, T(p) \rangle \geq 2\langle c_j, p \rangle (1 - \langle c_j, p \rangle).$$

If $p_0$ assigns positive probabilities to generators of $G$ then $\langle c_j, p_0 \rangle > 0$ and condition A2 is fulfilled.

EXAMPLE 2. From the elementary fact that when a coin is tossed $k$ times, the probability of an odd number of heads is $[1 - (1 - 2p)^k]/2$, one can verify the conditions of the theorem, to show that $p_n \to 1/2$ with probability one. It is perhaps interesting to note that when $k$ is even the transformation $T(p)$
is concave; when $k$ is odd, it is concave to the left of $1/2$ and convex to the right of $1/2$.

EXAMPLE 3. From the assumption of random mating it follows that $T(p) = p(1 - ps)/(1 - p^2s - (1 - p)^2t)$, from which it easily follows that 0 and 1 are fixed points of $T$. If $s$ and $t$ are both positive or both negative, then $q^* = t/(s + t)$ is also a fixed point; otherwise 0 and 1 are the only fixed points. It is straightforward to show that when $s$ and $t$ are both positive, the interior point $t/(s + t)$ is attracting, so $p_n \to t/(s + t)$ with probability one. (Like Example 2, $T$ is concave to the left of $q^*$ and convex to the right.)

When $s$ is nonpositive and $t$ is positive, the fixed point at 1 is attracting, and conversely in the case when $s$ is positive and $t$ nonpositive. If $s = t = 0$, every point in $[0,1]$ is a fixed point, the sequence $p_n$ is a martingale, which converges with probability one to a random limit. In the case when both $s$ and $t$ are negative, the fixed point at $t/(s + t)$ is not attracting. It seems intuitively clear that $p_n$ must converge to 0 or 1, but this does not seem to follow from Theorem 2 without an additional argument.

ACKNOWLEDGMENT. The authors would like to thank Persi Diaconis for suggesting this problem in the first place, Steve Lalley for suggesting we find a more general formulation of our original result, which dealt only with Example 1, and a referee whose careful reading has prevented us from making at least one egregious error in the formulation of Theorem 2. This research has been partially supported by the National Science Foundation and by the U.S.-Israel Binational Science Foundation.
