## A Proofs

## A. 1 Proof of Theorem 1

We start by showing that $\left\{A_{j}^{*}, X_{j}^{*}\right\}$ are independence if and only if $\left(N_{1}^{*}, \ldots, N_{K}^{*}\right) \mid M^{*}$ has a multinomial distribution. Any permutation of the ages is equally likely since the indices of individuals in the sample are non-informative, and therefore

$$
\begin{equation*}
\operatorname{pr}\left(\left\{A_{j}^{*}=a_{j}^{*}\right\}_{j=1}^{M^{*}} \mid M^{*}=m^{*}\right)=\frac{\prod_{k=1}^{K} n_{k}^{*}!}{m^{*}!} P\left(N_{1}^{*}=n_{1}^{*}, \ldots, N_{K}^{*}=n_{K}^{*} \mid M^{*}=m^{*}\right) \tag{A.1}
\end{equation*}
$$

where $n_{k}^{*}=\sum_{j=1}^{m^{*}} I\left(a_{j}^{*}=a_{k}\right)$. Under our model, and conditionally on $\left\{A_{j}^{*}\right\}$, the sojourn times $\left\{X_{j}^{*}\right\}$ are independent having the distribution $\operatorname{pr}\left(X_{j}^{*} \leq x \mid A_{j}^{*}=a\right)=G(x) / \bar{G}(a-)$ for $a \leq x$. Thus, the joint density of $\left(\left\{A_{j}^{*}\right\},\left\{X_{j}^{*}\right\}\right)$ conditionally on $\left\{M^{*}=m^{*}\right\}$ at points satisfying $\left\{a_{j}^{*} \leq x_{j}^{*}\right\}$ is

$$
\begin{align*}
& \frac{\prod_{k=1}^{K} n_{k}^{*}!}{m^{*}!} P\left(N_{1}^{*}=n_{1}^{*}, \ldots, N_{K}^{*}=n_{K}^{*} \mid M^{*}=m^{*}\right) \prod_{j=1}^{m^{*}} d G\left(x_{j}^{*}\right) \bar{G}\left(a_{j}^{*}-\right) \\
& =\frac{\prod_{k=1}^{K} n_{k}^{*}!}{m^{*}!} P\left(N_{1}^{*}=n_{1}^{*}, \ldots, N_{K}^{*}=n_{K}^{*} \mid M^{*}=m^{*}\right) \prod_{j=1}^{m^{*}} d G\left(x_{j}^{*}\right) \prod_{k=1}^{K}\left\{\bar{G}\left(a_{k}-\right)\right\}^{-n_{k}^{*}} . \tag{A.2}
\end{align*}
$$

Independence means that the above density can be written as a product of the joint probabilities of $\left(A_{j}^{*}, X_{j}^{*}\right)$, and by Equation (2) of the paper, this product is proportional to $\prod_{j=1}^{m^{*}} d G\left(x_{j}^{*}\right) \prod_{k=1}^{K}\left\{\operatorname{pr}\left(A_{j}=a_{k}\right)\right\}^{n_{k}^{*}}$. By equating the latter product to (A.2) we see that $\left(N_{1}^{*}, \ldots, N_{K}^{*}\right) \mid M^{*}=m^{*}$ has the distribution $\operatorname{Mult}\left(m^{*}, p_{1}^{*}, \ldots, p_{K}^{*}\right)$, where $p_{k}^{*} \propto P(A=$ $\left.a_{k}\right) \bar{G}\left(a_{k}-\right)$. On the other hand, if $\left(N_{1}^{*}, \ldots, N_{K}^{*}\right) \mid M^{*}$ has a multinomial distribution, it is readily seen that (A.2) is a product of terms depending on $j$, hence the pairs are independent. This completes the first step of the proof.

The main part of the theorem now follows from the following lemma that is of interest of its own

Lemma 1. Let $\left(N_{1}, \ldots, N_{K}\right)$ be a vector of random variables taking values in $\mathbb{N}^{K}$, where $\mathbb{N}$ denotes the non-negative integers, and assume that

$$
\begin{equation*}
N_{1}^{*}, \ldots N_{K}^{*} \mid N_{1}, \ldots, N_{K} \sim \Perp_{k=1}^{K} \operatorname{Bin}\left(N_{k}, \pi_{k}\right), \tag{A.3}
\end{equation*}
$$

that is, $\left(N_{1}^{*}, \ldots, N_{K}^{*}\right)$ are obtained by coordinate-wise thinning as follows: conditioned on $\left(N_{1}, \ldots, N_{K}\right)$ the variables $N_{1}^{*}, \ldots, N_{K}^{*}$ are independent with $N_{k}^{*} \mid N_{1}, \ldots, N_{K} \sim \operatorname{Bin}\left(N_{k}, \pi_{k}\right)$ for some parameters $\pi_{k} \in[0,1], k=1, \ldots, K$.

The following two conditions are equivalent
Condition A: $\left(N_{1}^{*}, \ldots, N_{K}^{*} \mid \sum_{k=1}^{K} N_{k}^{*}=m^{*}\right) \sim \operatorname{Mult}\left(m^{*}, p^{*}=\left(p_{1}^{*}, \ldots, p_{K}^{*}\right)\right)$ for each $m^{*}$, for some probability vector $p^{*}$.
Condition B: $\left(N_{1}, \ldots, N_{K} \mid \sum_{k=1}^{K} N_{k}=m\right) \sim \operatorname{Mult}\left(m, p=\left(p_{1}, \ldots, p_{K}\right)\right)$ for each $m$ for some probability vector $p$.

Remark 1. Let $M=\sum_{k=1}^{K} N_{k}$, and Let $M^{*}=\sum_{k=1}^{K} N_{k}^{*}$. If $\mu_{k}=E\left(N_{k}\right)$ then $E\left(N_{k}^{*}\right)=\mu_{k} \pi_{k}$. Now if Condition $A$ holds then $E\left(N_{k}^{*} \mid M^{*}\right)=M^{*} p_{k}^{*}$ and therefore $E\left(N_{k}^{*}\right)=E\left(M^{*}\right) p_{k}^{*}$, and it follows that $p_{k}^{*}=\mu_{k} \pi_{k} / \sum_{i} \mu_{i} \pi_{i}$. Also, $\mu_{k}=E(M) p_{k}$, and we conclude that

$$
\begin{equation*}
p_{k}^{*}=p_{k} \pi_{k} / \sum_{i} p_{i} \pi_{i} . \tag{A.4}
\end{equation*}
$$

Proof of Lemma 1. We first prove that Condition $\mathrm{B} \Rightarrow$ Condition A. Let $\left(N_{1}, \ldots, N_{K}\right) \sim P_{0}$ be some vector that satisfies Condition B. Given $M=\sum_{k=1}^{K} N_{k}$, construct new variables on a common probability space, $\left(N_{1 i}, \ldots, N_{K i}\right) \sim \operatorname{Mult}\left(1,\left(p_{1}, \ldots, p_{K}\right)\right)$ independent for $i=$ $1, \ldots, M$. Obviously, $\sum_{i=1}^{M}\left(N_{1 i}, \ldots, N_{K i}\right) \sim P_{0}$. Further, construct $\left(N_{1 i}^{*}, \ldots, N_{K i}^{*}\right) \mid\left(N_{1 i}, \ldots, N_{K i}\right)$ independently such that $N_{k i}^{*} \mid\left(N_{1 i}, \ldots, N_{K i}\right) \sim \operatorname{Bin}\left(N_{k i}, \pi_{k}\right)$ and set
$\left(N_{1}^{*}, \ldots, N_{K}^{*}\right)=\sum_{i=1}^{M}\left(N_{1 i}^{*}, \ldots, N_{K i}^{*}\right)$. Obviously, $\left(N_{1}^{*}, \ldots, N_{K}^{*}\right)$ satisfies (A.3) when conditioning is on $\sum_{i=1}^{M}\left(N_{1 i}, \ldots, N_{K i}\right)$. Now
$\left(N_{1 i}^{*}, \ldots, N_{K i}^{*}, N_{1 i}-N_{1 i}^{*}, \ldots, N_{K i}-N_{K i}^{*}\right) \sim \operatorname{Mult}\left(1,\left(p_{1} \pi_{1}, \ldots, p_{K} \pi_{K}, p 1\left(1-\pi_{1}\right), \ldots, p_{K}\left(1-\pi_{K}\right)\right)\right)$
are independent for $i=1, \ldots, M$ so their sum is multinomial, and hence its marginals (given their totals), with probabilities given by (A.4).

We now prove that Condition $\mathrm{A} \Rightarrow$ Condition B .
Setting $N^{*}=\left(N_{1}^{*}, \ldots, N_{K}^{*}\right)$ and $t=\left(t_{1}, \ldots, t_{K}\right)$, we compute the generating function $g_{N^{*}}(t)=E\left(\prod_{k} t_{k}^{N_{k}^{*}}\right)$ in two ways. First, using condition A we have

$$
E\left(\prod_{k} t_{k}^{N_{k}^{*}} \mid M^{*}\right)=\sum_{i_{1}+\ldots+i_{K}=M^{*}}\binom{M^{*}}{i_{1} \ldots i_{K}} \prod_{k}\left(p_{k}^{*} t_{k}\right)^{i_{k}}=\left(\sum_{k=1}^{K} p_{k}^{*} t_{k}\right)^{M^{*}}=\left(\sum_{k=1}^{K} p_{k}^{*} t_{k}\right)^{\sum_{k} N_{k}^{*}} .
$$

We compute the expectation of the latter expression to obtain $g_{N^{*}}(t)$ by first conditioning on $\left(N_{1}, \ldots, N_{K}\right)$ using (A.3) and then taking expectation with respect to $\left(N_{1}, \ldots, N_{K}\right)$. We readily obtain $E\left\{\left(\sum_{k=1}^{K} p_{k}^{*} t_{k}\right)^{\sum_{k} N_{k}^{*}} \mid\left(N_{1}, \ldots, N_{K}\right)\right\}=\prod_{k} E\left(s^{X_{k}}\right)$, where $s=\sum_{k=1}^{K} p_{k}^{*} t_{k}$ and $X_{k} \sim$ $\operatorname{Bin}\left(N_{k}, \pi_{k}\right)$. The latter binomial generating function is given by $E\left(s^{X_{k}}\right)=\left(1-\pi_{k}+\pi_{k} s\right)^{N_{k}}$ and we conclude that

$$
\begin{equation*}
g_{N^{*}}(t)=E\left\{\prod_{k}\left(1-\pi_{k}+\pi_{k} s\right)^{N_{k}}\right\}=g_{N}\left(1-\pi_{1}+\pi_{1} s, \ldots, 1-\pi_{K}+\pi_{K} s\right) . \tag{A.5}
\end{equation*}
$$

We compute $g_{N^{*}}$ again by first conditioning on $\left(N_{1}, \ldots, N_{K}\right)$ as follows:

$$
\begin{align*}
g_{N^{*}}(t) & =E\left\{E\left(\prod_{k} t_{k}^{N_{k}^{*}} \mid N_{1}, \ldots, N_{K}\right)\right\}=E\left\{\prod_{k}\left(1-\pi_{k}+\pi_{k} t_{k}\right)^{N_{k}}\right\} \\
& =g_{N}\left(1-\pi_{1}+\pi_{1} t_{1}, \ldots, 1-\pi_{K}+\pi_{K} t_{K}\right) \tag{A.6}
\end{align*}
$$

From (A.5) and (A.6) it follows that $g_{N}\left(1-\pi_{1}+\pi_{1} t_{1}, \ldots, 1-\pi_{K}+\pi_{K} t_{K}\right)$ is constant over the set $T_{s}=\left\{t: \sum_{k=1}^{K} p_{k}^{*} t_{k}=s\right\}$ for any $s$, and for fixed $\pi_{1}, \ldots, \pi_{K}$ we can write

$$
\begin{equation*}
g_{N}\left(1-\pi_{1}+\pi_{1} t_{1}, \ldots, 1-\pi_{K}+\pi_{K} t_{K}\right)=g_{N}\left(1-\pi_{1}+\pi_{1} s, \ldots, 1-\pi_{K}+\pi_{K} s\right)=h(s) . \tag{A.7}
\end{equation*}
$$

Recall

$$
\left.\frac{\partial^{n_{1}} \cdots \partial^{n_{K}}}{\partial t_{1}^{n_{1}} \cdots \partial t_{K}^{n_{K}}} g_{N}(t)\right|_{t=0}=\prod_{k} n_{k}!P\left(N_{1}=n_{1}, \ldots, N_{K}=n_{K}\right)
$$

In the same way

$$
\begin{array}{r}
\left.\frac{\partial^{n_{1}} \cdots \partial^{n_{K}}}{\partial t_{1}^{n_{1}} \cdots \partial t_{K}^{n_{K}}} g_{N}\left(1-\pi_{1}+\pi_{1} t_{1}, \ldots, 1-\pi_{K}+\pi_{K} t_{K}\right)\right|_{\left\{t_{k}=\left(\pi_{k}-1\right) / \pi_{k}, k=1, \ldots, K\right\}} \\
=\prod_{k}\left(\pi_{k}^{n_{k}} n_{k}!\right) P\left(N_{1}=n_{1}, \ldots, N_{K}=n_{K}\right) \tag{A.8}
\end{array}
$$

On the other hand from (A.7), and recalling $s=\sum_{k=1}^{K} p_{k}^{*} t_{k}$ we have

$$
\begin{align*}
&\left.\frac{\partial^{n_{1}} \cdots \partial^{n_{K}}}{\partial t_{1}^{n_{1}} \cdots \partial t_{K}^{n_{K}}} g_{N}\left(1-\pi_{1}+\pi_{1} t_{1}, \ldots, 1-\pi_{K}+\pi_{K} t_{K}\right)\right|_{\left\{t_{k}=\left(\pi_{k}-1\right) / \pi_{k}, k=1, \ldots, K\right\}} \\
&=\prod_{k}\left(p_{k}^{*}\right)^{n_{k}} h^{(m)}\left(\sum_{k} p_{k}^{*}\left(\pi_{k}-1\right) / \pi_{k}\right) \tag{A.9}
\end{align*}
$$

where $h^{(m)}$ denotes the $m$ th derivative of $h$ defined in (A.7), and $m=\sum_{k} n_{k}$. Set $\sum_{k} p_{k}^{*}\left(\pi_{k}-\right.$ $1) / \pi_{k}=\eta$. From (A.8) and (A.9) it follows that

$$
\begin{equation*}
P\left(N_{1}=n_{1}, \ldots, N_{K}=n_{K}\right)=h^{(m)}(\eta) \prod_{k}\left(\frac{p_{k}^{*}}{\pi_{k}}\right)^{n_{k}} \prod_{k} \frac{1}{n_{k}!}, \tag{A.10}
\end{equation*}
$$

and

$$
\begin{equation*}
P\left(N_{1}+\ldots+N_{K}=m\right)=h^{(m)}(\eta) \frac{1}{m!}\left(\sum_{k} \frac{p_{k}^{*}}{\pi_{k}}\right)^{m} \tag{A.11}
\end{equation*}
$$

so we conclude that

$$
\begin{equation*}
P\left(N_{1}=n_{1}, \ldots, N_{K}=n_{K} \mid N_{1}+\ldots+N_{K}=m\right)=\binom{m}{n_{1} \ldots n_{k}} \prod_{k}\left(\frac{p_{k}^{*}}{\pi_{k}} / \sum_{k} \frac{p_{k}^{*}}{\pi_{k}}\right)^{n_{k}} \tag{A.12}
\end{equation*}
$$

which is multinomial as required, with parameters that agree with (A.4).
Finally, the independent case is established by the following lemma, which is similar to a characterization of the Poisson distribution given by Chatterji (1963).
Lemma 2. Let $N_{1}, \ldots, N_{K}$ be independent random variables taking values in $\mathbb{N}$. Then, $\left(N_{1}, \ldots, N_{K} \mid\right.$ $\left.\sum_{k=1}^{K} N_{k}=m\right) \sim \operatorname{Mult}\left(m, p=\left(p_{1}, \ldots, p_{K}\right)\right)$ for each $m$ for some probability vector $p$, if and only if $N_{k} \sim \operatorname{Poisson}\left(c p_{k}\right)$ for some positive $c$.
Proof. The fact that for $N_{k} \sim \operatorname{Poisson}\left(c p_{k}\right)$ independent $\left(N_{1}, \ldots, N_{K} \mid \sum_{k=1}^{K} N_{k}=m\right) \sim \operatorname{Mult}(m, p)$ is well known. Assume $\left(N_{1}, \ldots, N_{K} \mid \sum_{k=1}^{K} N_{k}=m\right) \sim \operatorname{Mult}(m, p)$. For $K=2,1 \leq a \leq m$, and $k=1,2$,

$$
\frac{p_{k}}{1-p_{k}} \frac{m-a+1}{a}=\frac{\operatorname{pr}\left(N_{k}=a \mid N_{1}+N_{2}=m\right)}{\operatorname{pr}\left(N_{k}=a-1 \mid N_{1}+N_{2}=m\right)}=\frac{\operatorname{pr}\left(N_{k}=a\right) \operatorname{pr}\left(N_{3-k}=m-a\right)}{\operatorname{pr}\left(N_{k}=a-1\right) \operatorname{pr}\left(N_{3-k}=m-a+1\right)}
$$

which for $a=m$ gives for any $m$

$$
\frac{\operatorname{pr}\left(N_{k}=m\right)}{\operatorname{pr}\left(N_{k}=m-1\right)}=\frac{p_{k}}{1-p_{k}} \frac{\operatorname{pr}\left(N_{3-k}=1\right)}{\operatorname{pr}\left(N_{3-k}=0\right)} \frac{1}{m}=\frac{c_{k}}{m},
$$

a ratio which implies $N_{k} \sim \operatorname{Poisson}\left(c_{k}\right)$. It is easy to see directly that $c_{k}=E\left(N_{k}\right)=p_{k} E\left(N_{1}+\right.$ $\left.N_{2}\right)$, hence $c=E\left(N_{1}+N_{2}\right)$. For $K>2$ one can prove $N_{k} \sim \operatorname{Poisson}\left(c p_{k}\right)$ by writing $N_{-k}=$ $\sum_{j \neq k} N_{j}$ and using $\left(N_{k}, N_{-k}\right) \mid\left\{\sum_{j=1}^{K} N_{j}=m\right\} \sim \operatorname{Mult}\left(m, p_{k}, 1-p_{k}\right)$.

## A. 2 Proofs of asymptotic results

Sketch of proof of Theorem 2. Recall that $\left\{X_{k i}\right\}$ are independent and identically distributed and are independent of $\left\{N_{k}\right\}$. Denote the true parameter value by $\theta_{0}$. By (5), with $X^{*} \sim$ $G^{*}\left(\cdot ; \theta_{0}\right)$,

$$
\begin{equation*}
\frac{1}{M^{*}} \ell(\theta)=\frac{\frac{1}{\nu} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} I\left(a_{k} \leq X_{k i}\right) \log \frac{w\left(X_{k i}\right) g\left(X_{k i} ; \theta\right)}{\beta_{\theta}}}{\frac{1}{\nu} \sum_{k=1}^{K} \sum_{j=1}^{N_{k}} I\left(a_{k} \leq X_{k i}\right)} \rightarrow E_{\theta_{0}}\left[\log \left\{g^{*}\left(X^{*} ; \theta\right)\right\}\right] \tag{A.13}
\end{equation*}
$$

in probability, where the limit is obtained as follows. Starting with the denominator and recalling that $N_{k} /\left(\nu \eta_{k}\right) \rightarrow 1$ in probability, the law of large numbers implies

$$
\begin{equation*}
\sum_{k=1}^{K} \frac{1}{\nu} \sum_{i=1}^{N_{k}} I\left(a_{k} \leq X_{k i}\right)=\sum_{k=1}^{K} \eta_{k} \frac{N_{k}}{\nu \eta_{k}} \frac{1}{N_{k}} \sum_{i=1}^{N_{k}} I\left(a_{k} \leq X_{k i}\right) \rightarrow \sum_{k=1}^{K} \eta_{k} \bar{G}_{\theta_{0}}\left(a_{k}-\right)=\beta_{\theta_{0}} . \tag{A.14}
\end{equation*}
$$

The same reasoning applied to the numerator of (A.13) yields

$$
\begin{align*}
& \sum_{k=1}^{K} \eta_{k} \frac{N_{k}}{\nu \eta_{k}} \frac{1}{N_{k}} \sum_{i=1}^{N_{k}} I\left(a_{k} \leq X_{k i}\right) \log \frac{w\left(X_{k i}\right) g\left(X_{k i} ; \theta\right)}{\beta_{\theta}} \rightarrow \sum_{k=1}^{K} \int_{0}^{\infty} \eta_{k} I\left(a_{k} \leq x\right) \log \left\{g^{*}(x ; \theta)\right\} d G\left(x ; \theta_{0}\right) \\
& =\int_{0}^{\infty} \sum_{k=1}^{K} \eta_{k} I\left(a_{k} \leq x\right) \log \left\{g^{*}(x ; \theta)\right\} d G\left(x ; \theta_{0}\right)=\beta_{\theta_{0}} \int_{0}^{\infty} \log \left\{g^{*}(x ; \theta)\right\} \frac{w(x) d G\left(x ; \theta_{0}\right)}{\beta_{\theta_{0}}} \\
& =\beta_{\theta_{0}} \int_{0}^{\infty} \log \left\{g^{*}(x ; \theta)\right\} d G^{*}\left(x ; \theta_{0}\right)=\beta_{\theta_{0}} E_{\theta_{0}}\left[\log \left\{g^{*}\left(X^{*}, \theta\right)\right\}\right] . \tag{A.15}
\end{align*}
$$

Equations (A.15) and (A.14) imply (A.13). Identifiability and the information inequality assert that $E_{\theta_{0}}\left[\log \left\{g^{*}\left(X^{*}, \theta\right)\right\}\right]$ obtains its maximum at $\theta=\theta_{0}$; standard arguments guarantee the existence of a consistent sequence of roots (e.g., Lehmann and Casella 1998).

Example A. 1 (Inconsistency of the independence likelihood estimator). Consider the model $X_{k i} \sim \operatorname{Exp}(\theta)$ with $K=2, a_{1}=0, a_{2}=1$ and $\eta_{1}=\eta_{2}$, the exchangeable case. It is easy to see that $X_{k i}^{*}-k+1 \sim \operatorname{Exp}(\theta)$. Simple calculations show that the independence likelihood estimator, $\hat{\theta}$, solves the equation

$$
\frac{1}{\hat{\theta}}+\frac{e^{-\hat{\theta}}}{1+e^{-\hat{\theta}}}=\frac{N_{1}^{*}}{N_{1}^{*}+N_{2}^{*}} \bar{X}_{1}^{*}+\frac{N_{2}^{*}}{N_{1}^{*}+N_{2}^{*}} \bar{X}_{2}^{*},
$$

where $\bar{X}_{k}^{*}=\left(N_{k}^{*}\right)^{-1} \sum_{i=1}^{N_{k}^{*}} X_{k i}^{*},(k=1,2)$. As $\nu \rightarrow \infty, \bar{X}_{k}^{*} \rightarrow k-1+\theta^{-1}, k=1,2$, and $N_{k}^{*} / N_{k} \rightarrow e^{-\theta a_{k}}$ in probability, so the estimating equation is approximately

$$
\frac{1}{\hat{\theta}}+\frac{e^{-\hat{\theta}}}{1+e^{-\hat{\theta}}} \approx \frac{1}{\theta}+\frac{e^{-\theta}}{\frac{N_{1}}{N_{2}}+e^{-\theta}} .
$$

The independence likelihood estimator is consistent if $N_{1} / N_{2} \rightarrow \eta_{1} / \eta_{2}=1$ in probability, but not otherwise. As a concrete example, let $N_{k}$ be independent and $N_{k}=\nu / 4$ or $3 \nu / 4$ with probability $1 / 2$ each so that $N_{1} / N_{2}$ takes the values $1 / 3,1$, and 3 with corresponding probabilities $1 / 4,1 / 2$, and $1 / 4$, and the estimator converges to a non-degenerate random variable, and therefore is inconsistent.

Proof of Theorem 3. Using consistency, Taylor expansion of $0=\partial \ell\left(\hat{\theta}_{\nu}\right) / \partial \theta$ around $\theta_{0}$, and standard arguments yield the approximation

$$
\begin{equation*}
M^{1 / 2}\left(\hat{\theta}_{\nu}-\theta_{0}\right) \approx \frac{M^{-1 / 2} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} \frac{\partial}{\partial \theta} h_{k}\left(X_{k i} ; \theta_{0}\right)}{-M^{-1} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} \frac{\partial^{2}}{\partial \theta^{2}} h_{k}\left(X_{k i} ; \theta_{0}\right)} \tag{A.16}
\end{equation*}
$$

The conditions on $N_{1}, \ldots, N_{K}$ imply $N_{k} / M \rightarrow \eta_{k}$ in probability and the denominator of (A.16) converges to $-\sum_{k=1}^{K} \eta_{k} E_{\theta_{0}}\left[\partial^{2} h_{k}\left(X, \theta_{0}\right) / \partial \theta^{2}\right]$. The analysis of the numerator is more complicated:

$$
\begin{equation*}
M^{-1 / 2} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} \frac{\partial}{\partial \theta} h_{k}\left(X_{k i} ; \theta_{0}\right)=\sum_{k=1}^{K} M^{-1 / 2} \sum_{i=1}^{N_{k}}\left(\frac{\partial}{\partial \theta} h_{k}\left(X_{k i} ; \theta_{0}\right)-c_{k}\right)+M^{-1 / 2} \sum_{k=1}^{K} c_{k} N_{k} . \tag{A.17}
\end{equation*}
$$

A multivariate version of the proof in Rényi (1957) of Anscombe's Theorem and $N_{k} /\left(\eta_{k} M\right) \rightarrow 1$ in probability imply that

$$
\frac{N_{k}^{1 / 2}}{\left(\eta_{k} M\right)^{1 / 2}} \frac{1}{N_{k}^{1 / 2}} \sum_{i=1}^{N_{k}}\left(\frac{\partial}{\partial \theta} h_{k}\left(X_{k i} ; \theta_{0}\right)-c_{k}\right)
$$

converge jointly for $k=1, \ldots, K$ to independent mean zero normal variables.
Therefore, in (A.17),

$$
\begin{equation*}
\sum_{k=1}^{K} \frac{\eta_{k}^{1 / 2}}{\left(\eta_{k} M\right)^{1 / 2}} \sum_{i=1}^{N_{k}}\left(\frac{\partial}{\partial \theta} h_{k}\left(X_{k i} ; \theta_{0}\right)-c_{k}\right) \rightarrow W \tag{A.18}
\end{equation*}
$$

in distribution, where $W \sim N\left(0, \sum_{k=1}^{K} \eta_{k} \operatorname{var}_{\theta_{0}}\left\{\partial h_{k}\left(X ; \theta_{0}\right) / \partial \theta\right\}\right)$.
Turning to the second term in (A.17), we have $M^{-1 / 2} \sum_{k=1}^{K} c_{k} N_{k}=M^{-1 / 2} \sum_{k=1}^{K} c_{k}\left(N_{k}-\eta_{k} \nu\right) \rightarrow$ $V$ in distribution, where we used the facts that $\sum_{k} \eta_{k} c_{k}=0$, proved below, and $\nu^{-1} M \rightarrow 1$ in probability. Now, (7) is obtained from (A.16) by

$$
\begin{equation*}
\frac{M^{*}}{M}=\sum_{k=1}^{K} \frac{N_{k}}{M} \frac{1}{N_{k}} \sum_{j=1}^{N_{k}} I\left(a_{k} \leq X_{k j}\right) \rightarrow \sum_{k=1}^{K} \eta_{k} \bar{G}\left(a_{k}-; \theta_{0}\right)=\beta_{\theta_{0}} . \tag{A.19}
\end{equation*}
$$

It remains to show $\sum_{k} \eta_{k} c_{k}=0$ and independence of $V$ and $W$. Interchanging the order of integration and differentiation and recalling $\sum_{k=1}^{K} \eta_{k} I\left(a_{k} \leq x\right)=w(x)$, we obtain as in (A.15)
$\sum_{k=1}^{K} \eta_{k} c_{k}=\left.\frac{\partial}{\partial \theta} \int_{0}^{\infty} \sum_{k=1}^{K} \eta_{k} I\left(a_{k} \leq x\right) \log \left\{g^{*}(x ; \theta)\right\} d G\left(x ; \theta_{0}\right)\right|_{\theta=\theta_{0}}=\left.\beta_{\theta_{0}} \frac{\partial}{\partial \theta} E_{\theta_{0}}\left[\log \left\{g^{*}\left(X^{*}, \theta\right)\right\}\right]\right|_{\theta=\theta_{0}}$,
which vanishes since the maximum of $E_{\theta_{0}}\left[\log \left\{g^{*}\left(X^{*}, \theta\right)\right\}\right]$ is attained at $\theta=\theta_{0}$.
To prove independence of $W$ and $V$, note that the assumptions on the entrance process imply $N_{k} /\left(\eta_{k} M\right) \rightarrow 1$ in probability, and by (A.18), it suffices to prove asymptotic independence of $U^{(\nu)}$ and

$$
W^{(\nu)}=\sum_{k=1}^{K}\left(\frac{\eta_{k}}{N_{k}}\right)^{1 / 2} \sum_{j=1}^{N_{k}}\left(\frac{\partial}{\partial \theta} h_{k}\left(X_{k j} ; \theta_{0}\right)-c_{k}\right) .
$$

Given $\epsilon>0$ let $n_{0}$ be such that $n_{k}>n_{0}$ for all $k$ implies $\left|\operatorname{pr}\left(W^{(\nu)} / \sigma \leq t \mid\left\{N_{k}=n_{k}\right\}\right)-\Phi(t)\right|<\epsilon$, where $\sigma^{2}=\sum_{k=1}^{K} \eta_{k} \operatorname{var}_{\theta_{0}}\left\{\partial h_{k}\left(X ; \theta_{0}\right) / \partial \theta\right\}$, and let $\nu$ be such that $\operatorname{pr}\left(N_{k}^{(\nu)}>n_{0}\right.$ for all $\left.k\right)>1-\epsilon$. For $n_{k}$ 's $>n_{0}$ we have

$$
\operatorname{pr}\left(W^{(\nu)} / \sigma \leq t, U^{(\nu)} \leq u \mid\left\{N_{k}=n_{k}\right\}\right) \leq(\Phi(t)+\epsilon) I\left(\sum_{k=1}^{K} c_{k} \frac{n_{k}-\eta_{k} \nu}{\nu^{1 / 2}} \leq u\right) .
$$

Unconditioning by summing over all $\left\{n_{k}\right\}$ readily yields

$$
\operatorname{pr}\left(W^{(\nu)} / \sigma \leq t, U^{(\nu)} \leq u\right) \leq(\Phi(t)+\epsilon) \operatorname{pr}\left(U^{(\nu)} \leq u\right)+\epsilon
$$

A similar lower bound completes the proof.
Proof of Theorem 4. Since $N_{k} \rightarrow \infty$ in probability, the weak law of large numbers yields

$$
\frac{1}{N_{k}} \sum_{i=1}^{N_{k}} w\left(X_{k i}\right)^{-1} I\left(a_{k} \leq X_{k i} \leq x\right) \rightarrow \gamma_{k}(x)
$$

in probability, which holds also for $x=\infty$. In addition, the assumptions imply $N_{k} / M \rightarrow \eta_{k}$ in probability, and by (9) and (10), $\hat{G}(x) \rightarrow \sum_{k=1}^{K} \eta_{k} \gamma_{k}(x) / \sum_{k=1}^{K} \eta_{k} \gamma_{k}(\infty)=G(x)$.
Proof of Theorem 5. By (9)

$$
\begin{equation*}
M^{1 / 2}(\hat{G}(x)-G(x))=\frac{M^{-1 / 2} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} w\left(X_{k i}\right)^{-1} I\left(a_{k} \leq X_{k i}\right)\left[I\left(X_{k i} \leq x\right)-G(x)\right]}{M^{-1} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} w\left(X_{k i}\right)^{-1} I\left(a_{k} \leq X_{k i}\right)} . \tag{A.20}
\end{equation*}
$$

The denominator in (A.20) converges in probability to 1 since $N_{k}^{-1} \sum_{i=1}^{N_{k}} w\left(X_{k i}\right)^{-1} I\left(a_{k} \leq\right.$ $\left.X_{k i}\right) \rightarrow \gamma_{k}(\infty)$ by the Law of Large Numbers, $N_{k} / M \rightarrow \eta_{k}$, and $\sum_{k=1}^{K} \eta_{k} \gamma_{k}(\infty)=1$, see (10).

Setting

$$
S_{k i}(x)=w\left(X_{k i}\right)^{-1} I\left(a_{k} \leq X_{k i}\right)\left[I\left(X_{k i} \leq x\right)-G(x)\right],
$$

we have $E\left\{S_{k i}(x)\right\}=c_{k}(x)$, and $\sum_{k} \eta_{k} c_{k}(x)=0$. As in (A.19), $M^{*} / M \rightarrow \beta$ in probability; also, in probability, $M / \nu \rightarrow 1$ and we obtain that $M^{* 1 / 2}\{\hat{G}(x)-G(x)\}$ is asymptotically equivalent to

$$
\begin{equation*}
\beta^{1 / 2} \sum_{k=1}^{K} \frac{1}{M^{1 / 2}} \sum_{i=1}^{N_{k}}\left\{S_{k i}(x)-c_{k}(x)\right\}+\beta^{1 / 2} \sum_{k=1}^{K} \frac{c_{k}(x)\left(N_{k}-\eta_{k} \nu\right)}{\nu^{1 / 2}} . \tag{A.21}
\end{equation*}
$$

We have $M^{-1 / 2} \sum_{i=1}^{N_{k}}\left\{S_{k i}(x)-c_{k}(x)\right\} \rightarrow N\left(0, \eta_{k} \sigma_{k}^{2}(x)\right)$ in distribution, and therefore,

$$
\sum_{k=1}^{K} M^{-1 / 2} \sum_{i=1}^{N_{k}}\left\{S_{k i}(x)-c_{k}(x)\right\} \xrightarrow{\mathcal{D}} N\left(0, \sum_{k=1}^{K} \eta_{k} \sigma_{k}^{2}(x)\right) .
$$

Independence of $W(x)$ and $V(x)$ follows by reasons as in the proof of Theorem 3.

## A. 3 Asymptotic normality in the multi-parameter case

Suppose that $\theta$ is $p$-dimensional and that the independence likelihood estimator is consistent. Under standard regularity conditions, Taylor approximation gives

$$
\begin{equation*}
M^{1 / 2}\left(\hat{\theta}-\theta_{0}\right) \approx M H^{-1}\left(\theta_{0}\right) \frac{1}{M^{1 / 2}} D_{\ell}\left(\theta_{0}\right) \tag{A.22}
\end{equation*}
$$

where $D_{\ell}\left(\theta_{0}\right)=\left(\partial \ell\left(\theta_{0}\right) / \partial \theta_{1}, \ldots, \partial \ell\left(\theta_{0}\right) / \partial \theta_{p}\right)^{t}$ and $H\left(\theta_{0}\right)=\left(\partial^{2} \ell\left(\theta_{0}\right) / \partial \theta_{s} \partial \theta_{t}\right)$ is the $p \times p$ matrix of second derivatives. Under conditions as in Theorem 3

$$
M H^{-1}\left(\theta_{0}\right)=\left(\sum_{k=1}^{K} \frac{N_{k}}{M} \frac{1}{N_{k}} \sum_{i=1}^{N_{k}} \frac{\partial^{2}}{\partial \theta_{s} \partial \theta_{t}} h_{k}\left(X_{k i} ; \theta_{0}\right)\right)^{-1} \rightarrow\left(\sum_{k=1}^{K} \eta_{k} E_{\theta_{0}}\left\{\frac{\partial^{2}}{\partial \theta_{s} \partial \theta_{t}} h_{k}\left(X, \theta_{0}\right)\right\}\right)^{-1}
$$

in probability.
Next, write $M^{-1 / 2} D_{\ell}\left(\theta_{0}\right)$ as a sum of two vectors:

$$
\begin{equation*}
\left(M^{-1 / 2} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} \frac{\partial}{\partial \theta_{j}} h_{k}\left(X_{k i} ; \theta_{0}\right)\right)=\left(\sum_{k=1}^{K} M^{-1 / 2} \sum_{i=1}^{N_{k}}\left(\frac{\partial}{\partial \theta_{j}} h_{k}\left(X_{k i} ; \theta_{0}\right)-c_{k j}\right)\right)+M^{-1 / 2}\left(\sum_{k=1}^{K} N_{k} c_{k j}\right), \tag{A.23}
\end{equation*}
$$

where $c_{k j}=E_{\theta_{0}}\left\{\partial h_{k}\left(X ; \theta_{0}\right) / \partial \theta_{j}\right\}$, and note that

$$
\left(M^{-1 / 2} \sum_{i=1}^{N_{k}}\left(\frac{\partial}{\partial \theta_{1}} h_{k}\left(X_{k i} ; \theta_{0}\right)-c_{k 1}\right), \ldots, M^{-1 / 2} \sum_{i=1}^{N_{k}}\left(\frac{\partial}{\partial \theta_{p}} h_{k}\left(X_{k i} ; \theta_{0}\right)-c_{k p}\right)\right), \quad k=1, \ldots, K
$$

converge jointly to independent zero mean normal vectors with corresponding covariances $\eta_{k} \operatorname{cov}\left\{\partial h_{k}\left(X ; \theta_{0}\right) / \partial \theta_{s}, \partial h_{k}\left(X ; \theta_{0}\right) / \partial \theta_{t}\right\}$. Therefore, the first term on the right hand side of (A.23) satisfies $\left(\sum_{k=1}^{K} M^{-1 / 2} \sum_{i=1}^{N_{k}}\left(\partial h_{k}\left(X_{k i} ; \theta_{0}\right) / \partial \theta_{j}-c_{k j}\right)\right) \rightarrow W$ in distribution, where

$$
\begin{equation*}
W \sim N_{p}\left(0, \sum_{k=1}^{K} \eta_{k} \operatorname{cov}\left\{\frac{\partial}{\partial \theta_{s}} h_{k}\left(X ; \theta_{0}\right), \frac{\partial}{\partial \theta_{t}} h_{k}\left(X ; \theta_{0}\right)\right\}\right) . \tag{A.24}
\end{equation*}
$$

The second term in (A.23) vanishes if the $N_{k}$ 's are constant, and otherwise can be treated as in the single parameter case.

## B Asymptotics with $K$

We study the asymptotic properties of the independence likelihood estimator in the following setting. There is a sequence $\left\{A_{k}\right\}_{k=1}^{K}$ of entrance points, a sequence $\left\{N_{k}\right\}_{k=1}^{K}$ of non-negative integer numbers, and a sequence $\left\{X_{k i}\right\}_{k=1, i=1}^{K, N_{k}}$ of lifetimes. We assume that the sequences are independent, each consisting of independent and identically distributed random variables. Specifically, we assume $A_{k} \sim W, N_{k} \sim P$, and $X_{k i} \sim G$, with the technical identifiability requirement that $W\left(x_{\min }\right)>0$, where $x_{\min }$ is the left limit of the support of $G$. We assume that $\nu:=E\left(N_{k}\right)<\infty$ and study the independence likelihood estimator when $K \rightarrow \infty$. This model assumes exchangeability because the distribution of $N_{k}$ is independent of $k$. The analysis is much simpler than in the setting considered in the paper as the likelihood (5) in the paper becomes a sum of $K$ independent and identically distributes random variables and $K \rightarrow \infty$.

First recall that the marginal law of the $X^{*}$ s is $d G^{*}(x)=W(x) d G(x) / \beta$, where here the weight function is given by $W=P(A \leq x)$, and $\beta=P(A \leq X)$. We prove consistency and asymptotic normality for the parametric case. As in the proof of Theorem 2, we show that

$$
\begin{equation*}
\frac{1}{M^{*}} \ell(\theta)=\frac{\frac{1}{\nu K} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} I\left(A_{k} \leq X_{k i}\right) \log \frac{W\left(X_{k i}\right) d G\left(X_{k i} ; \theta\right)}{\beta_{\theta}}}{\frac{1}{\nu K} \sum_{k=1}^{K} \sum_{j=1}^{N_{k}} I\left(A_{k} \leq X_{k i}\right)} \rightarrow E_{\theta_{0}}\left[\log \left\{d G^{*}\left(X^{*} ; \theta\right)\right\}\right] \tag{B.1}
\end{equation*}
$$

in probability. Starting with the denominator, we have that $\sum_{j=1}^{N_{k}} I\left(A_{k} \leq X_{k i}\right) k=1, \ldots, K$ are independent and identically distributed random variables with expectation $\nu \beta$ by Wald's

Lemma, so by the law of large numbers, the denominator converges to $\beta_{\theta}$. Similarly,

$$
\sum_{i=1}^{N_{k}} I\left(A_{k} \leq X_{k i}\right) \log \frac{W\left(X_{k i}\right) d G\left(X_{k i} ; \theta\right)}{\beta_{\theta}}
$$

are independent and identically distributed with expectation

$$
\nu \int \log \frac{W(x) d G(x ; \theta)}{\beta_{\theta}} W(x) d G(x)=\beta_{\theta} E_{\theta_{0}}\left[\log \left\{d G^{*}\left(X^{*} ; \theta\right)\right\}\right] .
$$

Using again the law of large numbers, (B.1) is obtained, and the proof of consistency follows the arguments in Theorem 2.

The asymptotic distribution is simpler than in Theorem 3. Denote

$$
h(X, A ; \theta)=\frac{\partial}{\partial \theta} I(A \leq X) \log \frac{W(X) d G\left(X ; \theta_{0}\right)}{\beta_{\theta_{0}}} .
$$

Starting with a term similar to (A.16), we have:

$$
\begin{equation*}
K^{1 / 2}\left(\hat{\theta}_{K}-\theta_{0}\right) \approx \frac{\frac{1}{K^{1 / 2}} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} \frac{\partial}{\partial \theta} h\left(X_{k i}, A_{k} ; \theta_{0}\right)}{\frac{-1}{K} \sum_{k=1}^{K} \sum_{i=1}^{N_{k}} \frac{\partial^{2}}{\partial \theta^{2}} h\left(X_{k i}, A_{k} ; \theta_{0}\right)} \tag{B.2}
\end{equation*}
$$

The denominator converges to $-\nu E_{\theta_{0}}\left\{\partial^{2} h\left(X, A ; \theta_{0}\right) / \partial \theta^{2}\right\}$. For the numerator, note that

$$
\begin{aligned}
E_{\theta_{0}}\left\{\frac{\partial}{\partial \theta} h\left(X_{k i}, A_{k} ; \theta_{0}\right)\right\} & =E_{\theta_{0}}\left\{\frac{\partial}{\partial \theta} I(A \leq X) \log \frac{W(X) d G\left(X ; \theta_{0}\right)}{\beta_{0}}\right\} \\
& =E_{\theta_{0}}\left\{\frac{\partial}{\partial \theta} \log d G^{*}\left(X ; \theta_{0}\right) W(X)\right\} \\
& =\beta_{\theta_{0}} E_{\theta_{0}}\left\{\frac{\partial}{\partial \theta} \log d G^{*}\left(X^{*} ; \theta_{0}\right)\right\}=0,
\end{aligned}
$$

so the numerator converges to a zero mean normal variable with variance

$$
\operatorname{var}_{\theta_{0}}\left(\sum_{i=1}^{N_{k}} \frac{\partial}{\partial \theta} h\left(X_{k i}, A_{k} ; \theta_{0}\right)\right)=\nu \operatorname{var}_{\theta_{0}}\left(\frac{\partial}{\partial \theta} h\left(X, A ; \theta_{0}\right)\right)
$$

Thus, unlike the setting where $K$ is fixed and $\nu \rightarrow \infty$, the asymptotic distribution is always normal.

Remark 2. A similar analysis applies for the case where the number of independent crosssectional samples increases, that is, $K$ is fixed, $N_{k h}$ is the number of patients in sample $h$ who entered at time $-a_{k}$, and $h \rightarrow \infty$.

## C Asymptotic distribution of $V$ - examples

Example C. 1 (Independent $N_{k}$ 's, Normal limit). Theorem 3 implies that $M^{* 1 / 2}\left(\hat{\theta}_{\nu}-\theta_{0}\right)$ is asymptotically normal if $V$ is a normal random variable, possibly degenerate. This condition is also necessary by Cramér's Theorem, e.g., Feller (1971) p. 525, which says that a sum of independent random variables has a normal distribution if and only if the summands are normal. Suppose that $N_{k}$ 's are independent with $E\left(N_{k}\right)=\eta_{k} \nu$ and $\operatorname{var}\left(N_{k}\right)=\sigma_{k}^{2}$, then

$$
U^{(\nu)}=\sum_{k=1}^{K} \frac{c_{k}\left(N_{k}-\eta_{k} \nu\right)}{\sigma_{k}} \times\left(\frac{\sigma_{k}^{2}}{\nu}\right)^{1 / 2}
$$

If $\left(N_{k}-\eta_{k} \nu\right) / \sigma_{k} \rightarrow N(0,1)$ in distribution for $k=1, \ldots, K$, and $\sigma_{k}^{2} / \nu \rightarrow b_{k}$ in probability, then $V \sim N\left(0, \sum b_{k} c_{k}^{2}\right)$; this includes the case $N_{k} \sim \operatorname{Poisson}\left(\eta_{k} \nu\right)$ where $\operatorname{var}(V)=\sum \eta_{k} c_{k}^{2}$. A smaller variance is obtained when $N_{k} \sim \operatorname{Binomial}\left(\nu, \eta_{k}\right)$ with $\operatorname{var}(V)=\sum_{\eta} \eta_{k}\left(1-\eta_{k}\right) c_{k}^{2}$. By Cramér's Theorem, as $\left\{c_{k}\left(N_{k}-\eta_{k} \nu\right) / \sigma_{k}\right\}$ are independent, the condition $b_{k}^{1 / 2}\left(N_{k}-\eta_{k} \nu\right) / \sigma_{k} \rightarrow N\left(0, b_{k}\right)$ is necessary for $V$ and hence for the independence likelihood estimator to have a normal limit. If $b_{k}=0$, e.g., for constant $N_{k} \equiv \eta_{k} \nu$, then $\nu^{-1 / 2} \sum_{k=1}^{K} c_{k}\left(N_{k}-\eta_{k} \nu\right) \rightarrow 0$, so $V=0$.

Example C. 2 (Dependent $N_{k}$ 's). As a simple but natural example of a normal limit in the presence of dependence, let $N_{k}=N_{0}^{\prime}+N_{k}^{\prime}$, where $N_{0}^{\prime}, N_{1}^{\prime}, \ldots, N_{K}^{\prime}$ are such that $E\left(N_{k}\right)=\eta_{k} \nu$. We have $U=\nu^{-1 / 2} \sum_{k=1}^{K} c_{k}\left(N_{k}-\eta_{k} \nu\right)=\nu^{-1 / 2} \sum_{k=1}^{K} c_{k}\left\{N_{k}^{\prime}-E\left(N_{k}^{\prime}\right)\right\}+\nu^{-1 / 2} \sum_{k=1}^{K} c_{k}\left\{N_{0}^{\prime}-\right.$ $\left.E\left(N_{0}^{\prime}\right)\right\}$. It is now easy to construct models having the same marginal distribution of the $N_{k}$ 's, but with different asymptotic distributions of $V$ of Theorem 3, and therefore of the independence likelihood estimator. This is in contrast to consistency, which by Theorem 2 depends only on the marginal distributions of the cohort sizes. For example, the case of equal cohort sizes, $N_{1}=\cdots=N_{K} \sim F$ corresponds to $N_{1}^{\prime}=\cdots=N_{K}^{\prime}=0$ and $\eta_{k}=1 / K$, and recalling $\sum_{k} c_{k} \eta_{k}=0$ it is easy to see that $V=0$. On the other hand, if the $N_{k}^{\prime} \sim F^{\prime}$ 's are independent and $N_{0}^{\prime}=0$, then $N_{k}$ 's are independent having the same distribution $F$. In this case a nondegenerate normal limit was demonstrated above.

Example C. 3 (Multinomial model). Another natural model of dependent $N_{k}$ 's that leads to asymptotic normality is the following. See Remark 1 in the paper. Let $M=M^{(\nu)}$ satisfy $E(M)=\nu$, and $M / \nu \rightarrow 1$ in probability, corresponding to the assumptions of Theorem 3. If $\left(N_{1}, \ldots, N_{k}\right) \mid M \sim \operatorname{Mult}\left(M,\left(\eta_{1}, \ldots, \eta_{K}\right)\right)$, then $V$ is Gaussian. To see this, write $N_{k}=\sum_{j=1}^{M} I\left(Z_{j}=e_{k}\right)$, where $Z_{j} \sim \operatorname{Mult}\left(1,\left(\eta_{1}, \ldots, \eta_{K}\right)\right)$ independently, and $e_{k}$ is a vector of $K$ coordinates with the $k$ th being 1 and the rest 0 . Then, $\nu^{-1 / 2} \sum_{k=1}^{K} c_{k}\left(N_{k}-\eta_{k} \nu\right)=$ $\nu^{-1 / 2} \sum_{j=1}^{M} \sum_{k=1}^{K} c_{k} I\left(Z_{j}=e_{k}\right)$, which converges to the normal distribution by Anscombe's Theorem, see Rényi (1957).

Example C. 4 (The effect of dependence among the $N_{k}$ 's on $\left.\operatorname{var}(V)\right)$. If $\operatorname{pr}\left(N_{1}=\ldots=N_{K}\right)=1$ then $\operatorname{pr}(V=0)=1$, hence $\operatorname{var}(V)=0$. The latter condition on the $N_{k}$ 's is the strongest form of dependence. This leads to the question of whether in natural cases $\operatorname{var}(V)$ is decreasing as a function of a suitable measure of dependence among the $N_{k}$ 's. We restrict the discussion to the case that the $N_{k}$ 's have equal expectations and variances, so that $\eta_{k} \equiv 1 / K$, in which case $\sum_{k} c_{k}=0$; however, it is easy to generalize.

Let $R$ denote the correlation matrix of $\left(N_{1}, \ldots, N_{K}\right)$. Then $\operatorname{var}(V)$ is proportional to $c^{t} R c$, for $c=\left(c_{1}, \ldots, c_{K}\right)$. We consider two simple models for $R$ with a dependence parameter $\rho$, the intraclass correlation model, and the autoregressive model. For the intraclass correlation matrix $R=(1-\rho) I+\rho 11^{t}$, where 1 here denotes a column vector of ones of length $K$. We have $c^{t} 11^{t} c=0$ because $\sum_{k} c_{k}=0$, and therefore $c^{t} R c=(1-\rho) \sum_{k} c_{k}^{2}$, which is clearly decreasing in $\rho$ and hence so is $\operatorname{var}(V)$.

Next consider the first order autoregressive correlation matrix with entries $r_{i j}=\rho^{|i-j|}$. Ignoring a proportionality constant we have $\partial \operatorname{var}(V) / \partial \rho=c^{t} B c$, where $B=\partial R / \partial \rho$, having entries $b_{i j}=|i-j| \rho^{|i-j|-1}$. Since $b_{i j}=\lim _{t \downarrow 0} t^{-1}\left(1-e^{-t b_{i j}}\right)$ and $\sum_{k} c_{k}=0$, it is easy to see that $c^{t} B c \leq 0$, that is, $B$ is conditionally negative definite, provided the matrix with entries $e^{-t b_{i j}}$ is positive definite. For $\rho=1$ the latter matrix is again a first order autoregressive correlation matrix which is positive definite, and thus $\operatorname{var}(V)$ is decreasing in $\rho$ near 1. However by direct calculations one can see that for $K \geq 4$ we do not have monotonicity of $\operatorname{var}(V)$ for all $\rho$ 's.

Example C. 5 (Non-Normal limit). The limit of $\sum_{k=1}^{K} c_{k}\left(N_{k}-\nu\right) / \sqrt{\nu}$ may not be Normal, and may not exist. Let $N_{1}, N_{2}$ be independent with $E\left(N_{k}\right)=\nu / 2$, and assume that $\operatorname{pr}\left(N_{k}=\nu-a\right)=$ $\operatorname{pr}\left(N_{k}=\nu+a\right)=1 / 2$ for some $a=a(\nu)$. In order that $N_{k} / E\left(N_{k}\right) \rightarrow 1$ in probability, a must
satisfy $a / \nu \rightarrow 0$. Here $\eta_{1}=\eta_{2}=1 / 2$ implying $c_{1}+c_{2}=0$ and $\sum_{k=1}^{2} c_{k}\left(N_{k}-\nu / 2\right) / \nu^{1 / 2}=$ $c_{1}\left(N_{1}-N_{2}\right) / \nu^{1 / 2}$, which takes the values 0 or $\pm 2 a c_{1} / \nu^{1 / 2}$. For $a=\nu^{1 / 2}$ the limiting distribution is neither degenerate nor Normal, and for $a=\left(2+(-1)^{\nu}\right) \nu^{1 / 2}$ the limit does not exist.

## D Parametric models with covariates

Suppose that for each observed sojourn time, $X_{j}^{*}$, we observe covariates denoted by $Z_{j}^{*}$. We aim to estimate the conditional distribution $G(x \mid z ; \theta)$. The assumptions we made on the $X$ 's now apply to the pairs $(X, Z)$ 's. Conditioning on the observed covariates values $z_{j}^{*}$, the independence likelihood of (4) is replaced by

$$
\begin{equation*}
L(\theta)=\prod_{j=1}^{m^{*}} \frac{w\left(x_{j}^{*}\right) g\left(x_{j}^{*} \mid z_{j}^{*} ; \theta\right)}{\beta_{\theta}\left(z_{j}^{*}\right)}, \tag{D.1}
\end{equation*}
$$

where $\beta_{\theta}(z)=E_{\theta}\{w(X) \mid Z=z\}$, and the independence likelihood estimator $\hat{\theta}$ is the value of $\theta$ that maximizes (D.1). Consistency and asymptotic normality in the sense of Theorems 2 and 3 can be proved in the same way, where the assumptions on $g(x ; \theta)$ should hold for $g(x \mid z ; \theta)$, and in (6)-(8) $\beta_{\theta_{0}}=E\left\{\beta_{\theta_{0}}(Z)\right\}$. Also $h_{k}\left(X_{k i} ; \theta\right)$ as defined in (5) is replaced by $h_{k}\left(X_{k i}, Z_{k i} ; \theta\right)=I\left(a_{k} \leq X_{k i}\right) \log \left\{w\left(X_{k i}\right) g\left(X_{k i} \mid Z_{k i} ; \theta\right) / \beta_{\theta}\left(Z_{k i}\right)\right\}$; we shall not repeat the proofs.

## E Detailed results of simulation

We conducted a simulation study with $K=20$ entrance points $\left(a_{k}=k-1\right)$ and a Gamma lifetime distribution with mean 12 , variance 48 . We considered several models of moderate sample sizes with $E\left(N_{k}\right)=20$ for all $k, \beta=P(A \leq X)=0.5875$ and therefore $E\left(M^{*}\right)=$ $\beta E(M)=235$, and larger sample sizes with $E\left(N_{k}\right)=50$ for all $k$ and $E\left(M^{*}\right)=587$. We also considered a model with $E\left(N_{k}\right)$ 's varying between about 15 to 26 , and between 40 and 61 .

The following models for the distribution of $N_{k}$ were tested: independent Poisson entrance numbers; mixtures of Poissons: $1 / 2 \operatorname{Pois}(15)+1 / 2 \operatorname{Pois}(25)$ in the small sample size scenario, and $1 / 2 \operatorname{Pois}(43)+1 / 2 \operatorname{Pois}(57)$ in the large sample size scenario, which reflect moderate deviation from the Poisson model; $1 / 2 \operatorname{Pois}(10)+1 / 2 \operatorname{Pois}(30)$ and $1 / 2 \operatorname{Pois}(35)+1 / 2 \operatorname{Pois}(65)$, reflecting large deviation from the Poisson model; independent Geometric entrance numbers; a constant number of entrances at each point; a symmetric multinomial model with $M \equiv 400$ and $M \equiv$ 1000 for the small and large sample size scenarios, respectively; non-exchangeable $N_{k}$ 's, where entrances are independent following Poisson variables with $N_{k} \sim \operatorname{Pois}(\exp (3.27-0.027 k))$ in the small sample scenario, and $N_{k} \sim \operatorname{Pois}(\exp (4 \cdot 12-0 \cdot 021 k))$ in the large sample scenario. These number were chosen so that the means of the $N_{k}$ 's are around 20 and 50 respectively.

For each model, we simulated 1000 samples and estimated $G$ nonparametrically and parametrically in the $\operatorname{Gamma}(\alpha, \beta)$ family. In each framework and for each simulated sample, we calculated the conditional and independence likelihood estimates of $G$, and averaged over the 1000 replications to obtain estimates for the MSE at the $10,25,50,75$, and 90 percentiles of $G$. Results are provided in Table E.1. As expected, the results show a clear advantage for the independence likelihood approach when $N_{k}$ 's are Poisson, or when they are relatively stable, such as constant $N_{k}$ 's or mixtures with moderate deviation from the Poisson model, while for more variable $N_{k}$ 's, the conditional approach is preferable.

Figures E. 1 shows the ratio MSE(conditional)/MSE(independence likelihood) as a function of the variance of $N_{k}$. It shows that the ratio decreases with the variance, where the conditional approach and the independence likelihood approach are equally good when the variance is 2-3
times the expectation. It also reveals that the efficiency of the independence likelihood approach is maximal for the degenerate case, where $N_{k} \equiv N$.

| $E\left(N_{k}\right)$ | Model | Method | $G^{-1}(\cdot 10)$ | $G^{-1}(\cdot 25)$ | $G^{-1}(.50)$ | $G^{-1}(.75)$ | $G^{-1}(.90)$ |

Table E.1: Ratio of MSE of conditional and independent likelihood parametric and non-parametric estimators of $G$ at different percentiles, with $K=20$ entrance points, $E\left(N_{k}\right)=20$ or 50 , and lifetime distribution $G=$ Gamma with mean 12 and variance 48 . Models for the $N_{k}$ 's were (in order of appearance in the table): Poisson, mixture of Poisson variables $\operatorname{mix}(a, b)=1 / 2 \operatorname{Pois}(a)+1 / 2 \operatorname{Pois}(b)$, Geometric, Constant, exchangeable multinomial, and inhomogeneous Poisson with $N_{k} \sim \operatorname{Pois}(\exp (3 \cdot 27-0 \cdot 027 k))$ and $N_{k} \sim \operatorname{Pois}(\exp (4 \cdot 12-0 \cdot 021 k))$.

So far, here and in the paper, we considered the case that the sample comprise all individuals in the cross-sectional population. In the next simulation we study the effect of simple random sampling from a large cross-sectional population. As before, we consider 20 entrance points at times $0,-1, \ldots,-19$. The cohort sizes considered are independent negative binomial variables with expectation $\nu=5000$ and standard deviations varying between $0 \cdot 1 \nu$ and $0 \cdot 5 \nu$, Poisson $(\nu)$ where the standard deviation is $\sqrt{ } \nu$, and a degenerate distribution (standard deviation=0). Lifetimes were generated from a Gamma distribution with mean 12 and variance 48. This process generated the cross sectional population of about 50-60 thousand individuals according to the criterion $A \leq X$. From the cross-sectional population at time 0 , random samples of $m^{*}=400$ and $m^{*}=1000$ individuals were selected and the conditional/unconditional parametric/nonparametric estimators were calculated. The MSE ratio of the conditional to the
unconditional parametric estimators in the $0 \cdot 1,0 \cdot 5$, and $0 \cdot 9$ quantiles are compared in Table E. 2 for the various standard deviations. These are based on 1000 replications. The results are similar for non-parametric estimation and for the other simulation studies: the independence likelihood approach is more efficient for cohort sizes that have variance similar to the expectation or smaller, and the conditional approach is more efficient when the variance is much larger than the expectation.

| $m^{*}$ | SD= | 0 | $\sqrt{ } \nu$ | $0 \cdot 1 \nu$ | $0 \cdot 2 \nu$ | $0 \cdot 3 \nu$ | $0 \cdot 4 \nu$ | $0 \cdot 5 \nu$ |

| 400 | $q_{0.10}$ | $1 \cdot 20$ | $1 \cdot 12$ | 1.14 | 1.05 | 1.01 | $0 \cdot 80$ | 0.63 |
|  | $q_{0.50}$ | $1 \cdot 33$ | 1.20 | 1.21 | $1 \cdot 10$ | 0.98 | 0.78 | 0.55 |
|  | $q_{0.90}$ | $1 \cdot 29$ | $1 \cdot 29$ | $1 \cdot 21$ | $1 \cdot 15$ | 1.02 | 0.91 | $0 \cdot 69$ |
| 1000 | $q_{0.10}$ | $1 \cdot 13$ | $1 \cdot 17$ | 1.05 | 0.87 | 0.66 | 0.51 | 0.39 |
|  | $q_{0.50}$ | $1 \cdot 23$ | 1.26 | 1.09 | 0.86 | 0.61 | 0.45 | 0.31 |
|  | $q_{0.90}$ | $1 \cdot 27$ | 1.23 | $1 \cdot 12$ | 0.94 | 0.74 | 0.57 | $0 \cdot 41$ |

Table E.2: MSE ratio - parametric model. Cohorts sizes, all having expectation $\nu=5000$, are constant ( $\mathrm{SD}=0$ ), Poisson ( $\mathrm{SD}=\sqrt{ } \nu$ ) and Negative Binomial with varying standard deviations (SDs). Random sampling of $m^{*}=400$ and 1000 individuals from the cross-sectional population
